## Concepts

- If we have an experiment  $E_1$  (like flipping a coin) with a outcomes, followed by an experiment  $E_2$  (like rolling a die) with b outcomes, then the total number of outcomes for the composite experiment  $E_1E_2$  can be found by multiplying a with b (this is known as the **rule of product**):
- If we have an experiment  $E_1$  with a outcomes, followed by an experiment  $E_2$  with b outcomes, followed by an experiment  $E_n$  with z outcomes, the total number of outcomes for the composite experiment  $E_1E_2 \dots E_n$  can be found by multiplying their individual outcomes:
- There are two kinds of arrangements:
  - Arrangements where the order matters, which we call **permutations**.
  - Arrangements where the order doesn't matter, which we call **combinations**.
- To find the number of permutations when we're sampling without replacement, we can use the formula:
- To find the number of permutations when we're sampling without replacement and taking only k objects from a group of n objects, we can use the formula:
- To find the number of combinations when we're sampling without replacement and taking only *k* objects from a group of *n* objects, we can use the formula:

## Resources

• A tutorial on calculating combinations when sampling with replacement, which we haven't covered in this mission

• An easy-to-digest introduction to permutations and combinations
